

**Research question or idea:** Why do animals search for certain resources which are rare or scarce? Can the presence of certain resources be used to interpret suitable habitats for the species which use them?

**Species/system:** Primates and mycophagy (consumption of fungi)

**Geographic/temporal scope:** South America, Amazonia

I'm not sure about the temporal scale, some work has been done on the seasonal availability of fungi consumed by primates though so that could be an avenue.

**Biological motivation:** Optimal foraging, I'm interested in food selection and why animals seek out rare foods which may not have the nutritional benefits to outweigh the costs of seeking those foods. Resources often drive daily distance traveled so the biotically suitable area for a species may be closely tied to the presence of staple foods.

**Questions or uncertainties:** I'm worried I won't have enough data or the right type of data to create a robust answer for my question.
